Technical Report

A clear format for ideas, methods, and evidence

ABSTRACT

A research report should make its question, method, and evidence easy to find. This template provides a consistent structure for NJU-LINK technical reports, working papers, and research notes. A compact identity block, a restrained blue–violet palette, and a readable text column establish the visual hierarchy. The following pages demonstrate headings, author affiliations, citations, a vector figure, an equation, and a comparison table. This is a typesetting example; it does not describe an empirical study or report experimental results.

Keywords Research reports; reproducibility; scientific communication

1 Introduction

Start with the research problem and the observation that makes it worth investigating. Define the setting precisely enough for the reader to understand what is being measured, which assumptions matter, and where the proposed approach is expected to apply. A concrete example often communicates the motivation more effectively than a broad statement about the field.

Then connect the limitation of current practice, the idea that addresses it, and the evidence used to evaluate that idea. State each contribution at the level supported by the results. The method appears in Section 3; Table 1 summarizes what a comparison should specify.

The central question

What changes, why should that change help, and which observation would show that it works? Use this space for one research question or one supported takeaway, then develop the evidence in the body of the report.

2 Related Work

Organize prior work by the distinction relevant to the research question. Explain which assumptions, capabilities, or evaluation settings differ. For example, [Vaswani et al. \(2017\)](#) can be cited as part of a sentence; a parenthetical citation uses the complementary form ([Vaswani et al., 2017](#)). This reference demonstrates the bibliography style.

3 Method

Define the inputs, outputs, and assumptions, then describe the stages in Figure 1 in the order needed to reproduce the method.

Figure 1. An illustrative research workflow. Colors identify stages and do not encode measured values.

3.1 Notation and evaluation

For N examples with individual scores s_i , the arithmetic mean is

$$\bar{s} = \frac{1}{N} \sum_{i=1}^N s_i. \quad (1)$$

For Equation (1), specify the score’s unit and the handling of missing observations.

4 Experiments

State the data, baselines, and controlled variables before presenting results. Table 1 demonstrates the table style without synthetic performance numbers.

Table 1. A compact reporting checklist. Replace these rows with the study’s own comparisons.

Element	What to specify	Why it matters
Data	Source, split, and exclusions	Defines the evaluated population
Comparison	Baselines and shared settings	Makes differences interpretable
Measurement	Metric, unit, and aggregation	Connects values to the question
Uncertainty	Repeats and variation	Shows the stability of the result

5 Results and Analysis

Pair each claim with the comparison that supports it. Distinguish a measured difference from a proposed explanation of that difference.

6 Limitations

Describe the conditions under which the finding holds, the settings not evaluated, and the comparisons still needed.

7 Conclusion

Close with the supported finding, its practical implication, and the next experiment.

Appendix

A Reproducibility Details

Use the appendix for configurations, additional analyses, and details needed to reproduce the study. Appendix sections use lettered numbering; they can be referenced from the main text with the same cross-reference commands.

A.1 Configuration record

Record the information required to connect the result to a specific run:

1. the version of the data and the rule used to construct each split;
2. the implementation version, configuration, and random seeds;
3. the evaluation script, metric definitions, and aggregation procedure.

Using this template

Edit the title, authors, affiliations, and abstract at the beginning of `main.tex`. The original author, affiliation, abstract, and metadata commands are retained. The short Chinese starting point is `starter.tex`; the README explains the available settings.

A.2 Supporting material

Provide enough detail for another researcher to inspect the assumptions and repeat the analysis. Prefer descriptive figure captions and explicit units; use tables for comparisons and short paragraphs for interpretation.
